Department of Agricultural Economics, Extension and Rural Development,
University of Pretoria.

Abstract

This paper discusses the reasons for and effects of the dramatic expansion of chat production as a cash crop in the Hararghe Highlands of Ethiopia. Despite the Ministry of Agriculture's deliberate attempt to marginalize and openly discourage chat production, farmers continue shifting their scarce resources to chat production. Using data generated by a rural livelihood survey from 197 randomly selected households, economic and non-economic factors contributing to the expansion of chat production are identified and its food and nutritional security impact was analyzed. The case study confirms once more again the power of market incentives in encouraging agricultural activity of peasant farmers even in the absence of functional research and extension systems. The study shows that households producing chat have good food security and thus the situation presents a policy dilemma: should the government promote or discourage chat production?

1. Introduction

Chat (*Catha edulis*) is a perennial tree crop mainly grown in the Eastern Ethiopia. The people living in the Horn of Africa and in some Arab countries chew young and fresh leaves of chat as a stimulant. Very little is known about the effect of chat on human physiology. It is however said that chat increases the sugar level in blood and improves blood circulation. This provides energy, which help workers to withstand fatigue and improves concentration of students when they study.

The major production area of chat in Ethiopia is the Hararghe Highlands (hereafter HHs) located in Eastern Ethiopia. It has however been observed chat production has also been expanding in other regions especially in areas located south of the capital, Addis Ababa. In some areas of the HHs, in particular the chat-belt of Alemaya, it was

¹ Alemaya University, Ethiopia

² University of Pretoria, South Africa.

found that the area of cropland allocated to chat is as high as 75% of total arable land (Save the Children Fund/UK, 1996). In the survey area, cropland area allocated to chat ranges from 21% in Kuni (Chiro District) to 54% in Alemaya. It was also observed that the majority of irrigated land is allocated to chat production and in addition chat enterprise consumes most of the scarce organic manure in farm households. It is not uncommon to find farmers diverting part of inorganic fertilizers provided on credit by the Ministry of Agriculture (MoA) for crop production to chat production. Indeed, if Hararghe farmers have to be admired for their indigenous technical knowledge it has to be because of the way they manage their chat fields. Farmers have developed appropriate spacing, defoliation time, other cultural practices, variety selection and disease control methods including use of chemicals such as DDT. All of these were done independently without any government involvement or assistance from farmers' associations.

Both legal and illegal channels are used to export chat. The volume of chat exported legally from the HHs was about 200 metric tons (Mt) in 1948 and reached 1,400 Mt in 1958 (Klinge, 1998). According to the local branch of the National Bank of Ethiopia, the volume and value of chat exports from the region rose from 2, 746 Mt and 30.2 million birr³ in 1977 to 3, 496 Mt and 114.4 million birr in 1986 (National Bank of Ethiopia, 1986). Ethiopia earned 618.8 million birr in hard currency in the year 1999/2000 by exporting 15, 684 Mt of chat (National Bank of Ethiopia, 2001). Chat has become the second most important earner of foreign exchange next to coffee in 1999/2000 as shown in Figure 1.

³ birr is Ethiopian currency. 8.7 birr is approximately equal to 1.00 US dollar

Source: Developed from data reported by the National Bank of Ethiopia, 2001

Figure 1: Value of major export (in thousand birr)

The fact that chat production has replaced staple cereals and coffee is interesting for a number of reasons. Unlike coffee and cereals, chat has never directly benefited from research, extension advice and credit service. Besides its alleged effect on human health, the MoA is concerned that the expansion of chat production might have a negative repercussion on food security of households and on foreign exchange earnings of the country. Chat is also been blamed for decreased productivity as people waste valuable working time sitting and chewing it for hours. Empirical evidence is not yet available and it is not clear whether abusing chat is any different from abusing alcohol.

This paper examines the economic and non-economic factors contributing to the rapid expansion of chat production and empirically assesses the income, food security, and nutritional impact of growing chat at household level. To our knowledge, there is little empirical evidence on this issue partly because chat has deliberately been excluded

from any research agenda in Ethiopia. The only exception to this is a preliminary study conducted by the then Ethiopian Institute of Nutrition in the mid 1980s that found that although chat growers income was three times greater than non-chat growers, the nutritional status of preschoolers was the same among the chat-growers and the non-chat growers (Seyoum et al., 1986:40).

This paper is organized as follows: section two describes the study area and section three briefly describes the research method followed to obtain the necessary data. Section four and five present results of the analysis; and finally, section six draws major lessons from the case study and presents a policy challenge regarding the fate of the growing chat sector.

2. The Study Area

The study region is located in Eastern Ethiopia south of Djibouti and west of Hargessa town of Somalia. The Ethio-Djibouti railway passes through the region while good air connections exist with Addis Ababa, Djibouti and Somalia. A fairly good gravel road connects the HHs with neighboring regions. Sorghum and maize are the staple crops and coffee has traditionally been the single most important cash crop. Nevertheless, chat is replacing coffee in the HHs except in remote and inaccessible areas where coffee retains its importance. The HHs farming economy is further more characterized by small and fragmented land holdings caused by increasing population pressure.

3. Research Method

Both qualitative and quantitative data generated from a rural livelihood survey of 197 randomly selected households conducted between the mid March 2001 and the mid January 2002 form the database for the current analysis. Included in the quantitative survey were variables related to demography, resource endowment, income and expenditure, and grain available for consumption at household level. A once-off anthropometric assessment (age, sex, and height) of preschoolers (children aged between 6 and 60 months) was also taken from the same households who had preschool children at the time of the survey (a total of 103 households). The procedure recommended by the United Nations's Sub-Committee on Nutrition (Beaten et al., 1990) and Nutrition Guidelines by Médecins Sans Frontières (Arbelot

et al., 1995) was followed and a public health officer provided technical assistance in the execution of this component of the study.

4. Factors Contributing to the Expansion of Chat Production

There are a number of factors that are contributing to the expansion of chat production in the HHs. The first, perhaps the most important, is growing domestic and export markets for chat and improved access to these markets an improved transport network. The export market is substantial and expanding. This includes countries such as Djibouti, Somalia and some Arab countries such as Yemen. Chat is also exported to Europe, but is banned in Canada and the United States of America. The HHs' location and its superior transport network have played an important role in the expansion of chat since the product has to reach its final destination fresh and therefore fast transport is needed. In the domestic market, it is quite evident that chat chewing has become a recreation activity and now also forms part of the culture of the urban youth.

The export price of chat has also been rising since the mid 1970s (Gebissa, 1994 cited in Degefa and Nega, 2000). While chat enjoys a relatively stable price at the world market, coffee suffers from both fluctuating export volumes and prices. Coffee Berry Disease, the increasing prices of chemicals following the removal of subsidies under the structural adjustment program, and declining world coffee prices have all contributed to the decline of the Ethiopian coffee sector. Producing chat has thus become a viable and important alternative to ensure continued cash income. Chat has additional advantage because it can be harvested at least twice a year under rainfed agriculture while up to five harvests per year is possible under irrigation. This ensures that households have a well distributed flow of income.

Another economic factor for the growing interest in chat production is related to its cost of production relative to other competing enterprises. Labour is the most important cost item in the production of chat. Rapid population growth in the HHs has provided enough family labour or highly cheap hired labour for labour-intensive production, making chat production feasible. In the second place, chat is hardly affected by any disease except some damage by insects that can easily be controlled

by locally developed methods at little or no cost. Chat need for minimum off-farm inputs makes its production compatible with poor farmers' limited access to credit. Table 1 gives an overview of the related profitability of chat in the HHs economic systems.

Table 1: Income possibilities for staple food and major cash crops in the HHs

	Food crops		Cash crops			
	Sorghum	Maize	Coffee	Chat	Potato	Onion
Yield/ha – rainfed (kg)	700-1200	1000-1300	400-700	700-1000	5000-7000	3500-8000
Gross income/ha (birr)	560 – 1800	700- 1820	4800- 11200	16100-23000	7500-10500	9100-20800
Production cost	Low	Low	Low-high	Low	High	High
Average net income	Low	Low	Medium	High	Medium	Medium- high
Risk factor	Low- medium	Low- medium	High	Low	High	Medium- high

Source, Klingele, 1998

Economic considerations are very important in peasant farmers' resource allocation decisions, however, there are other equally important factors that should be accounted for to understand peasants' complex decision-making process. Risk is one such factor. Although the average precipitation in the HHs is generally considered adequate for viable rainfed agriculture, its amount and abnormal distribution exposes crops to frequent weather hazards (Storck, et al, 1997). Intercropping is one of the widely used indigenous strategies to manage risks associated with weather, diseases, and pests. Chat is less exposed to these risks and perfectly fit for intercropping unlike coffee. Chat is usually intercropped with sorghum, the crop preferred for its drought tolerance. In order to describe the extent of its resilience against the vagaries of weather the local people say, "Sorghum dies seven times and resurrects seven times."

Finally, the topography of the HHs coupled with cultivation of steep hillsides and diminishing vegetative covers make a critical problem. Although the land tenure insecurity is generally believed to discourage investment in soil improvement in the country (Rahmato, 1994), Hararghe farmers practice different soil conservation methods as a survival strategy. The farmers have always chosen soil and water conservation methods that take little land out of cultivation although the improved

conservation methods promoted by extension take more land (Sutcliffe, 1995). Thus, planting of chat hedgerows on steep slopes is preferred to the other methods by the farmers as an economically attractive conservation method that at the same time generates some income.

5. Effect of Chat Production on the Welfare of Households

5.1 Income effect

As the information presented in Table 1 implies, growing chat not only generates the highest revenue but also involves low production cost and risks. From this it follows that income of chat growers expected to be higher than income of non-chat growers as shown in Table 2. One should however keep in mind that the reliability of income data is always questionable in subsistence farming where record keeping is limited. To deal with this problem, proxy indicators of households' income such as livestock ownership, value of farm implements, expenditure, and ownership of houses with iron sheet cover have been recorded. Again the data shows that chat growers are significantly better-off than the non-growers in all the proxy indicators, validating the income data.

Table 2: Means of income associated variables for chat growers and non-chat growers in the HHs.

	Chat growers	Non- chat growers	F	Significance
Cash crop income	2499.95	444.84	34.56	.000
Total expenditure	2506.95	1226.57	18.201	.000
Value of farm implements	914.62	223.51	4.122	.044
Livestock owned in tropical livestock unit	2.72	1.70	19.7	.000
Percent with iron-sheet cover house	58.7%	40.6%		

Source: Computed from own survey data

5.2 The household food security effect of producing chat

The effect of cash crop production on food security and nutrition of farm households is less straightforward than the income effect discussed above. Whether increased income from cash crop production is translated to improved food security and nutritional status of households depends on a number of factors including expenditure behavior, gender relations, availability and prices of grain, etc. Cash crop production can result in deterioration of food security and nutritional status of households in

situation where expansion of cash crop production increases prices of staples or where male-headed households mainly spend the additional income from cash crops on non-food items (von Braun, et al., 1991; Kennedy et. al., 1992; von Braun and Kennedy, 1994).

From the qualitative and quantitative information presented in Table 3, it seems as if chat-growers are not just more food secure but also more food self-sufficient than the control group. Nevertheless, the table doesn't give sufficient information that enables one to make any conclusion regarding the relationship between households' food security status and producing chat.

Table 3: Food security indicators for chat and non-chat growers in the HHs.

	Chat growers	Non-chat growers
Level of self-sufficiency in staple crop		
Produce surplus	15.2%	11.4%
Self-sufficient	25.6%	11.4%
Self-insufficient	59.2%	77.1%
Years of food shortage in the past 5 years		
Never faced food shortage	44.8%	35.7%
One year	17.6%	17.1%
Two years	19.2%	18.6%
Three to five years	18.4%	28.6%
Net grain available per adult equivalent for consumption (kg)	255.2	214.2
Don't sell grain	56%	44.3%

Source: Own field survey

In order to test this intuitive interpretation, a logit maximum likelihood model was developed and estimated to rigorously explore the relationship between producing chat and food security status of the households. In addition to 'chat production' other explanatory variables included in the analysis were: gender, family size converted into adult equivalent, cropland area per adult equivalent, livestock ownership, access to extension, vegetables (the most important cash crop next to chat) production and participation in off-farm/nonfarm activities.

We opted for the binary logistic regression based on theoretical considerations and the nature of our dependent variable that assumes the value of one (food secure household) or zero (food insecure household) based on food security status of each household. Although there are alternative probability functions, such as probit

probability function that can accommodate dichotomous dependent variables, the logit probability function is usually preferred to the other models due to its mathematical simplicity, flexibility and ease of interpretation (Aldrich and Nelson, 1984; Gujarati, 1998).

Table 4: Model specification for determinants of food security of households in the HHs

Variable	Expected sign	Variable description
Gender of household head	+	Dummy, male-headed household = 1
Consumption unit	-	Family size converted to adult equivalent
Cropland size per adult equivalent	+	Cropland in hector/adult equivalent
Have access to extension	+	Dummy, favourable response = 1
Livestock ownership	+	In tropical livestock unit
Grow chat for market	+	Dummy, at least 10 % of total cropland area planted with chat = 1
Grow vegetables for market	+	Dummy, favourable response = 1
Participate in off/non farm activities	?	Dummy, favourable response = 1

Households' levels of income are often used in Ethiopia to measure food security status of households. Either an estimated level of income required for commanding food that would satisfy the minimum recommended daily calories intake, given typical national food consumption basket, or absolute poverty line estimated by adding allowances for basic nonfood needs on the former is used. However, there are a number of practical problems associated with this approach. In the first place, there is a conceptual difference between poverty and food insecurity (Devereux, 2000); secondly, the reliability of income data in subsistence farming where record keeping practice is almost nonexistent is questionable; and thirdly, the levels of income estimated by different studies (Government of Ethiopia, 1999; Emana, 2000) as adequate to acquire the recommended minimum calories for HHs are very different; and fourthly, the correlation between income, and food security and nutritional status of households is not always strong (Hoddinot, 2001). Poverty-line is also sensitivity to food prices change.

The net quantity of cereals available for consumption at household level is used as a proxy indicator of food security status of households in this study. Cereals consumption account for 70% (appendix) low income households in Ethiopia. It accounts for 74% of the calories of the average Ethiopian rural households and it is estimated that 236kg of cereals is needed per adult equivalent per year, based on the assumption that 1kg of cereals provides 3400 kcal, to meet the recommended

minimum calorie of 2 200 kilo calories per day (Emana, 2000). The same quantity was used as a cut-off point to distinguish households with/without food security.

The quantity of cereals available for consumption at household level was estimated from cereals produced, cereals bought and cereals sold, i.e., the net quantity of cereals *available for consumption = (cereals produced + cereals bought + cereals received as gift/transfer) – (cereals sold + gift and transfer given)*, ignoring the amount stored since households rarely store cereals beyond the beginning of the next cropping season in the study area. Data on cereals harvest and transaction was collected periodically from the end of one cropping season (March, 2001) to the beginning of the next harvest season (January, 2002).g United Nations Food and Agricultural Organization (1999) and Agren and Gibson (1968) indicates that cereals constitute 74% of the calories of the Ethiopian rural households and estimates that 236 kg of cereals is needed per adult equivalent per year to meet the recommended minimum calories of 2200 kcal per day.

Result of the analysis is given in Table 5. All the variables have theoretically expected signs. The goodness of fit of the model as measured by correct prediction of percent of originally grouped cases is high (75.4%) and Hosmer and Lemeshow test shows that the model fits the actual observation fairly well. Participation in off-farm/non-farm activities and access to extension are insignificant. The positive sign of access to extension coefficient shows a potentially positive contribution of extension to food security through increased productivity. The negative sign of off/nonfarm coefficient probably supports the hypothesis that households drawn into it by poverty than by choice (see Barrett et al., 2001). All the other variables are significant and positively related to food security status of households, but family size. Based on selected observations, we expected that producing chat contributes positively to food security of households. The results reported in Table 5 confirm this expectation with the finding ‘chat production’ increases the probability that a household would be food secure. However, it is clear from the results that land holding per adult equivalent makes a far greater contribution to household food security.

Further, field observation indicates that the decrease in land allocated to staple crops as a result of the expansion of production of chat is more than offset by increase in yield through the adoption of land productivity enhancing technologies financed by proceeds from chat sales and other cash crops. Descriptive analysis shows that 74.4 % of chat growers used chemical fertilizers for food crop production, whereas only 24.3% of non-chat growers used chemical fertilizers. Besides, 56 % of chat producers didn't sell grain for cash (Table 3). Season of sorghum harvest coincides with season of high prices for irrigated chat. Those who are self-insufficient buy grain from the market immediately after harvest at low prices for immediate consumption and reserve what they produce to consume when grain prices reach their peak in pre-harvest season commonly known as 'season of poverty'. Moreover, grain availability on the markets has never been a problem since the HHs geographically close to one of surplus grain producing regions, the Central Highlands. We can, thus, conclude that the expansion of chat production has improved chat-growing households' both production-based as well as income-based entitlement to food.

Table 5: Logistic estimation of determinants of food security status of households in the HHs

4.3 Effect of producing chat on the nutritional status of preschoolers

A multivariate linear regression analysis (dependent Variable: height for age Z) and binary logistic regression analysis were run to empirically establish the effect of producing chat on long-term preschoolers' nutritional status. Measuring the nutritional status of preschool children is, together with other demographic and health related variables, commonly used as a proxy for the nutritional status of the respective

households. Height and age data of the preschoolers was converted to a Z-score⁵ and the internationally accepted cutoff point (- 2Z or 2 standard deviation points) was used to distinguish the malnourished and the non-malnourished preschoolers. Similar methods are employed elsewhere (von Braun, et al., 1991; Kennedy et al., 1992; von Braun and Kennedy, 1994). Kirsten et al. (1998) used both Ordinary Least Square (OLS) method and logistic regression model, and Garrett and Ruel (1999) used two stage least square in addition to OLS to address simultaneity bias. Unfortunately, from the 197 sample households included in the livelihood study only 103 had preschoolers at the time of the survey. The sample size is obviously low for such study (the previous study by the Ethiopian Institute of Nutrition used a sample size of 389).

Although the limitation of small sample size should be considered while interpreting the results, the analysis indicates that producing chat has a positive effect on preschoolers' nutritional status that is significant at less than 2% (OLS) and at less than 7% (logit model). The livestock units owned is also positively and significantly related to preschoolers' nutritional status at less than 2% (OLS) and at less than 10 % (logit model). All the other non-significant variables have theoretically expected signs except birth-order of children. Participation in off-farm/non-farm activities coefficient changed from a negative in OLS to a positive in logistic model, but insignificant in both. R^2 , the measure of overall fit of the OLS model, is comparable to the other studies (cf. Garrett and Ruel, 1999). The logit model predicted about 71% of originally grouped cases correctly. Furthermore, prevalence of malnutrition among preschoolers, school age children and adolescents (less than 18 years old) taken together is 37.5% in Alemaya (highly chat dominated area), 45% in Sabale (moderate chat growing area) and 50% in Kuni (where chat is less important). This supports the results of the analysis.

⁵ Z score =
$$\frac{\text{Observed value} - \text{Median reference value}}{\text{Standard Deviation of reference population}}$$

Height for age value expressed in Z-score measures retardation in skeletal growth that is a reflection of nutritional inadequacy and unhealthy environment.

Table 6: OLS and Logistic estimation of determinants of long-term nutritional status of preschoolers in HHs

Variables	OLS estimation (y= height for age Z)		Logistic estimation (y =1 when the child is not malnourished)

6. Conclusions and Policy Dilemma.

The case study demonstrated that subsistence farmers respond to market incentives in terms of improved access to market opportunities and better prices more than is conventionally believed. The most important lesson that policy makers can learn from the chat case is that the provision of research and extension service is on its own insufficient to get smallholder agriculture ‘moving’. Delivering research and extension service will only bring the urgently needed quantum leap in the increase in production and productivity to feed mouths growing at unprecedented rate in Ethiopia and elsewhere in the Sub-Saharan Africa if and only if it is combined with creation of market incentives. At the heart of miracle of the Asian Green Revolution is the success of Borlaug in winning better prices (comparable to world prices) for producers through his persuasive power both in India and Pakistan (see Borlaug, 1988).

Expansion of chat production in the HHs of Ethiopia has mainly been driven by market incentives. Shifting the scarce land and other resources to chat has significantly increased rural income, positively contributed to food and nutrition

security of the households, and soil conservation. It has also become an additional source of the badly needed foreign exchange earnings for the country. According to a study conducted in the mid 1980s, about two –third of households in the HHs didn't have enough land to meet their minimum nutritional requirement (Adnew and Storck, 1992). A major shift to chat production and using proceeds from chat sales to finance the adoption of improved technology and fill grain deficit has prevented or postponed the total collapse of livelihoods in this part of the world.

The policy dilemma for the government is vested in two alternative policy scenarios. One option is to accept chat production as a major contributor to livelihoods of the households and to use part of the tax revenue it generates to support the enterprise. The second option is to continue considering chat as a 'drug' and perhaps enforce a shift to other cash crops as the previous government attempted in vain. The second option is the most difficult, and perhaps the most frightening one since it requires creating alternative livelihoods that can sustain people's life in such a land scarce area and where the population is still growing despite the level of hardship. Few non-farm job opportunities will exist in the absence of the chat sector since chat processing, packaging, transporting and distributing is currently the single most important source of alternative employment and income. The policy makers should also be reminded that serious negative health effects of smoking are scientifically well established yet the production and marketing of cigarettes has continued to protect income and employment. Indeed health impact of chat is not yet well established and likely to be tolerable!

Acknowledgements

The Alemaya University generously provided financial and logistic support for the research through the Agricultural Research and Training Project (ARTP). Mr. Haji Kadir oversaw the technical aspects of anthropometric measurements and Mrs. Tigist Abraham took the pain of walking with the survey team to each and every sample household houses to interview mothers on family planning, child feeding and health. She climbed mountains, enjoyed the rain, mud and the sun with the team voluntarily as a token of her value to her spouse (Tefera). We are grateful to all who contributed directly and indirectly to the success of the research including those whose names are not mentioned.
